The Problem

Repair or replace is a guess. Battery wear, drive health and thermals are hidden, and local part prices are scattered across classifieds. Working laptops get replaced; failing ones are repaired too late.

Our Solution

Fahes is a local-first desktop app. It reads battery, drive, RAM and thermal health, then ranks repair, upgrade, reuse, recycle or replace by cost per added year, waste hierarchy and CO2e - priced from real Jordanian data.

Target Impact

Longer device life, lower spend and less e-waste. Each device gets a verifiable second-life passport with QR, wipe attestation and recovered-materials estimate. Works offline in English and Arabic, with no account or telemetry.

Open Source AI & Development

AI Integration:

Small open-weight models run locally through Ollama - qwen3:4b, gemma3:4b or llama3.2:3b. The model only turns a sentence into validated filters: category, DDR, form factor, capacity, price and condition. A deterministic parser is the fallback; health, prices and compatibility are never model-generated. Localhost only, no cloud, no telemetry.

No model installed? The same query is parsed with rules, and the UI says so.

What We Built:

Working Electron app: Linux and Windows detection, health scoring, remedy engine, Jordanian price book, offline OpenSooq index with refresh and photos, impact ledger, Arabic RTL, second-life passport PDF and QR, wipe attestation, demo mode and packaging. Open source, MIT.
